

Surgical Patient Optimization Guideline Checklist Health Plan Level 3

The current state of the issue

Anemia and poor glycemic control are key modifiable risk factors that worsen perioperative outcomes in those undergoing major surgery. Both preoperative anemia and perioperative hyperglycemia are associated with longer hospital stays[i], increased costs, higher morbidity and mortality[ii],[iii], and worse recovery. Even mild anemia can affect 30-day outcomes, and perioperative glucose levels predict short-term mortality5F[iv], while evidence shows hyperglycemia impacts non-diabetic patients more negatively than those with diabetes. In Washington state, there is significant variation in practices regarding anemia management and glycemic optimization in patients with and without diabetes.

General

- ☐ Payment Redesign
 - ☐ Where feasible, integrate preoperative screening for anemia and glycemic control into quality programs for surgical optimization
 - ☐ Consider incentives for delivery systems that have accreditation from national organizations in patient blood management (e.g., The Joint Commission)
 - ☐ Consider including requirement of preoperative anemia optimization and intraoperative glycemic control protocols in centers of excellence models for surgical centers (e.g., total hip/total knee replacement, spine surgery, etc.)
 - ☐ Minimize penalties for appropriate delay of procedure when optimization not achieved
- ☐ Track relevant measures/metrics for glycemic control and anemia optimization. See Measurement section and Evaluation Framework

- ☐ Share data on the rate of preoperative screening for anemia and diabetes with providers and/or facilities for major elective procedures
 - ☐ For instance, provider- or facility-facing dashboards with specific rates of HbA1c screening and Hb/Hct screening for major elective procedures
