

Health Impacts of Extreme Heat & Wildfire Smoke Guideline Checklist Health Plans Level 3

The current state of the issue

Exposure to extreme heat, or summertime temperatures that are much hotter and/or humid than average, is a serious threat to population health and well-being. 2024 was the warmest year on record, with global temperatures 2.30 degrees Fahrenheit (1.28 degrees Celsius) above the National Aeronautics and Space Administration's (NASA) 20th century baseline. The number and length of heat waves has increased significantly since the 1960s. These trends are projected to continue and worsen in the coming decades, exposing more people to the harmful consequences of heat. Higher air temperatures increase wildfire likelihood, posing a serious threat to human health, ecosystems, and infrastructure. Wildfire smoke exposure increases all-cause mortality, impacts respiratory health, and may co-occur and interact with heat exposure to impact cardiorespiratory morbidity and mortality.

Incentives & Investments

- ☐ **Incent delivery systems** to reduce the number of health-related illnesses and exacerbations of chronic conditions occurring during warmer months

Resources

- The Bree Report is meant to supplement these resources.
