# Health Impacts of Extreme Heat & Wildfire Smoke Guideline Checklist Outpatient Clinic Healthcare Staff Level 3

### The current state of the issue

Exposure to extreme heat, or summertime temperatures that are much hotter and/or humid than average, [i] is a serious threat to population health and well-being. 2024 was the warmest year on record, with global temperatures 2.30 degrees Fahrenheit (1.28 degrees Celsius) above the National Aeronautics and Space administration's (NASA) 20th century baseline. [ii] The number and length of heat waves has increased significantly since the 1960s. [iii] These trends are projected to continue and worsen in the coming decades, exposing more people to the harmful consequences of heat. Higher air temperatures increase wildfire likelihood, posing a serious threat to human health, ecosystems, and infrastructure. Wildfire smoke exposure increases all-cause mortality, impacts respiratory health, and may co-occur and interact with heat exposure to impact cardiorespiratory morbidity and mortality. [iv] [v] [vi] [vii]

# **Equity**

J	<b>Develop a workflow to identify patients</b> that are at higher risk for heat-related illness and
	exacerbations of conditions due to heat and wildfire smoke
	Use ICD-10 codes, prescription and demographic information to automatically flag and add to
	registry
	Add patients at higher risk to a registry
	Take measures to protect privacy of patient information
	During warmer months, direct patients on the registry to a care manager (or similar
	professional) for personalized outreach before and during extreme heat and poor air quality
	Use tailored educational messaging for higher risk populations when triggered automatically
	during heat or wildfire smoke
